— CIRCUIT DESCRIPTION —

NOTE: Only the right channel will be described for simplicity since the left channel is identical.

The pre-driver and driver stages are DC coupled. The pre-driver (Q1) is a small signal silicon transistor; the driver (Q2) a drift-field germanium power type.

Fixed bias for Q1 (pre-driver) is provided by voltage divider resistors R6, R8, R4 and C4 are in a "bootstrap" connection with Q1. Since the AC swing at the emitter of Q1 follows the input signal, R4 is literally "bootstrapped" along with this signal, causing the effective value of R4 to be multiplied by the approximate beta of Q1. Q1 is used as a common emitter amplifier, directly driving Q2. The driver stage (Q2) provides no voltage gain but a large power gain to the power output stage via interstage coupling transformer T1.

Approximately 20 db of negative feedback from the final output stage is applied through C6 and R10 to the emitter of the pre-driver stage Q1. The use of negative feedback results in improved damping and reduced distortion of the audio signal.

The pre-driver stage (Q1) collector voltage provides the bias voltage for the driver stage, Q2. It can be seen that when the pre-driver collector voltage falls (high conduction) the base voltage of the driver also falls, thus driving this stage toward saturation. Therefore, under signal conditions, the driver may be driven from saturation to cut-off by the pre-driver stage.

Phase reversal necessary to drive the power output stage is obtained from the secondary windings of the driver transformer T1.

The final power output stage consists of a matched pair of DTG110 germanium transistors (Q3,Q5) and a matched pair of DTG110B germanium transistors (Q4,Q6) connected in a class B push-pull arrangement for high power gain and excellent linearity. A total of 200 Watts of EIA music power is taken from the collector-emitter busses of these matched transistor groups to drive the speaker systems directly. With a drive point potential on the collector-emitter buss nominally at 0 VDC, the signal swing is from near -45 VDC to near +45 VDC.

Emitter resistors R24 and R34 serve to compensate for differences between transistor parameters and the effects of ambient temperature variations. R16, R18, R20 and R22 form a biasing network for the power output transistors to keep their "no signal" condition slightly above cutoff to eliminate cross-over distortion.

Power transistors Q3 and Q5 are used in the common base mode and are directly driven by Q4 and Q6 collectors. Their purpose is to share the power supply voltage with the transformer driven transistors Q4 and Q6.

Capacitors C9 and C13 provide extra high frequency drive to Q3 and Q5 to maintain their power output at higher audio frequencies.

Note that all four DTG110 transistors are mounted on one extruded aluminum heat sink and that all four DTG110B transistors are mounted on the other.

Input AC power is applied to power transformer T3 and rectified in a solid state, full wave balanced bridge network. The secondary winding of the transformer has a grounded center tap in order to obtain both +45 volts and -45 volts from the rectified output. Note that the filter in the -45 volt line (C30) is mounted on a phenolic insulator to isolate the can from chassis ground.

When replacing power transistors, always observe the following precautions:

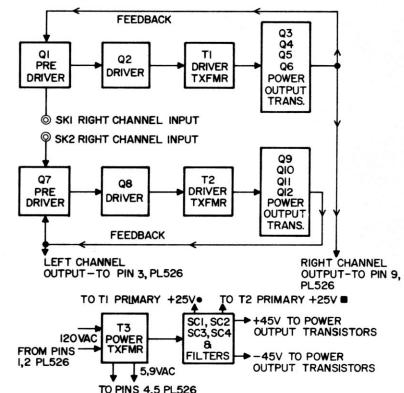

1. Use matched Beta, direct replacement types only.
2. Be sure to use silicon grease liberally on both sides of the mica insulators used under these transistors.
3. Be sure to snug down the power transistor to the heat sink evenly and firmly.
4. A momentary short across the output terminals of this amplifier will not damage the output stage. However, a prolonged shorted condition may cause serious damage to the amplifier.

#14 or #16 "Zip cord" is excellent for making up long extension speaker cables.

— TECHNICAL INFORMATION —

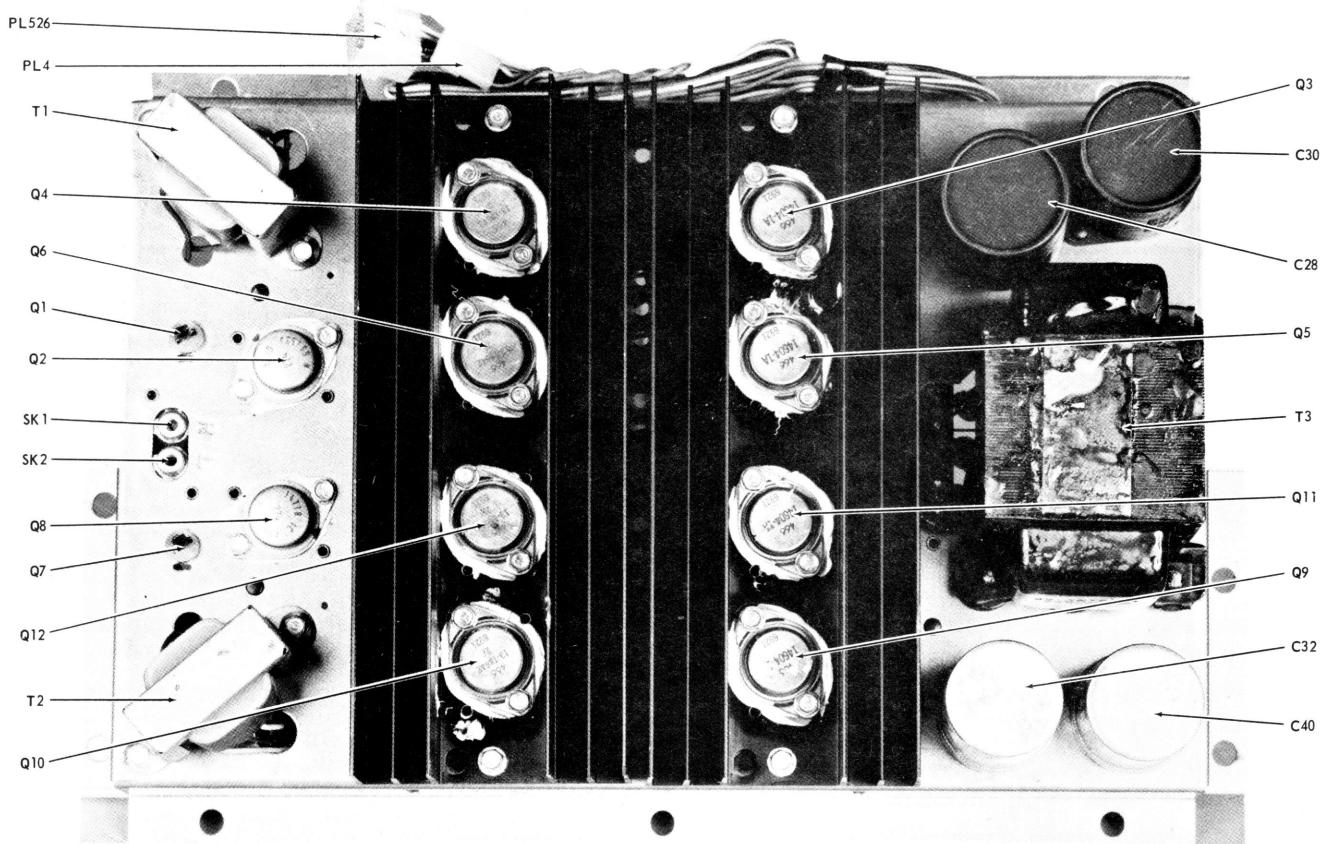

Sensitivity:	1.5 volts for 60 watts, each channel.
Frequency Response:	8 Hertz to 55kHz ± 3 db.
Cont. Sine Wave Pwr:	100 watts total at less than 0.7% T.H.D.
EIA Music Power:	200 watts total.
IHF Music Power:	160 watts total into 8 ohm load at less than 0.7% total harmonic distortion.
IM Distortion:	Less than 0.5% for 50 watts - each chan.
Peak Music Power:	Less than 0.5% for 320 watts total.
Power Response:	15 Hz to 20 kHz (Half Power Points)
Hum and Noise:	85db below 80 watts.
Load Impedance:	8 ohms.
Damping Factor:	20

— BLOCK DIAGRAM —

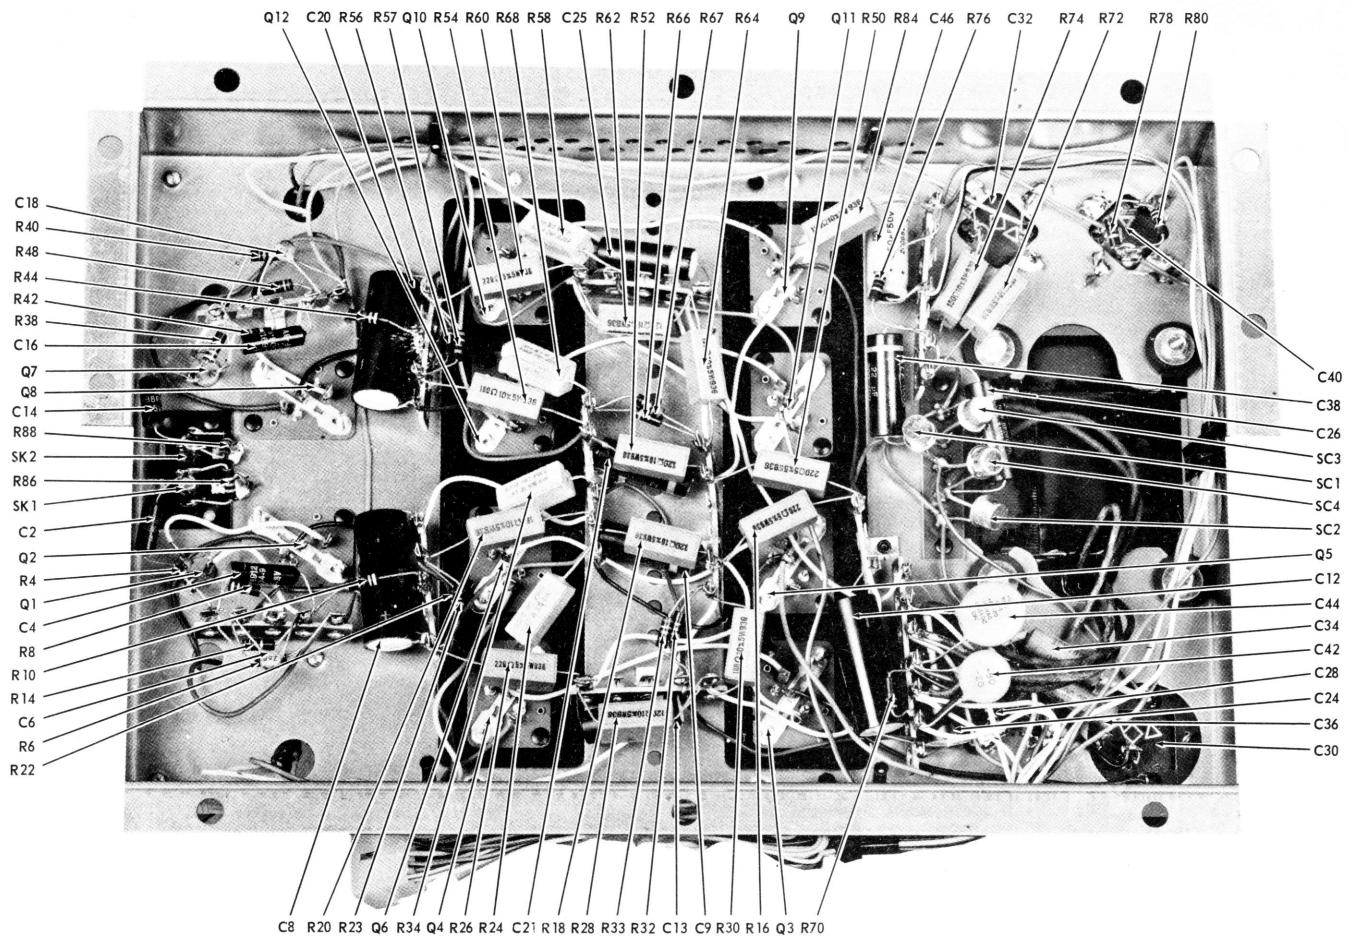

IMPORTANT: Always use genuine Sylvania replacement parts & tubes.
